Configuring high availability in ADSelfService Plus

ADSelfService Plus uses automated failover to support high availability in case of system and product failures. Essentially, this means that when ADSelfService Plus fails on one machine, another instance of ADSelfService Plus running on another machine automatically takes over.

Before configuring high availability in ADSelfService Plus, make sure that the following conditions are satisfied.

Condition 1: Download and install ADSelfService Plus on two separate machines.

If you already have ADSelfService Plus, update your installation to the latest build and make sure you download and install ADSelfService Plus on a second machine as well.

Condition 2: Both of the downloaded instances should:

- Run as a service.

- Have the same build architecture (32-bit or 64-bit) and build number.

- Be connected to the same domain and network.

- Have the domain configured using a service account with domain admin privileges.
  Note that domain admin privileges are only mandatory during the initial setup of high availability. Once high availability has been configured, the service account can be changed to one with lesser privileges based on the other features configured.

- Have uninterrupted sharing of the installation directory folder

Condition 3: The virtual IP address must lie in the same IP range as that of the primary and standby servers.

Condition 4: To enable high availability, you need to purchase the Failover and Secure Gateway Services Add-on. Buy now.

> **Important:** It is recommended that an external database server (supported databases are PostgreSQL and Microsoft SQL) is used for better high availability in ADSelfService Plus. Using the built-in PostgreSQL database could lead to database connectivity failure when the primary server fails, rendering the product non-functional.

Configuration steps

1. Log in to ADSelfService Plus with admin credentials.

2. Navigate to Admin ⟶ Enterprise Essentials ⟶High Availability.

3. Select Enable High Availability.

4. In the *Primary Server* section, the URL of the ADSelfService Plus server you are currently accessing (i.e., the primary server) will be autofilled.

5. In the *Standby Server* section, enter the:

    ○ Standby Server Name/IP of the ADSelfService Plus standby server.

    ○ Admin Username and Password of a super admin in the ADSelfService Plus standby server.

6. In the *Virtual IP* section, enter:

    ○ A Virtual IP Address with which you can access both the primary and standby servers.
        A virtual IP address is an unused static IP address.

    ○ An appropriate Virtual Host Name. A virtual host name is the alias given to the virtual IP address.

7. Click Save.

8. After successful configuration of high availability, a pop-up appears with Restart now and Restart later buttons. Clicking Restart now will automatically restart the ADSelfService Plus service in the primary and standby servers. If you click Restart later, you will have to manually restart the primary server first and then the standby server.

Important: Once high availability is enabled, you must:

- Update the **Access URL** with the virtual IP address value from step 6.

- Add the virtual IP address value to the *Admin Login* page's IP restriction list (if it is enabled) in **Logon Settings.**
